CSC 211: Computer Programming Pointers

Michael Conti

Department of Computer Science and Statistics University of Rhode Island

Fall 2024

So far ...

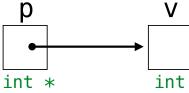

- Every variable/object (regardless of scope) exists at some memory location (memory address)
- Every memory address corresponds to a **unique location** in memory
- The compiler translates names into memory addresses when generating machine level code
- C++ allows programmers to manipulate variables/ objects and their memory addresses directly

Pointers

What is a pointer?

- A special type of variable whose value is the **memory address** of another variable
- · Pointers must be **declared** before use
 - ✓ pointer type **must** be specified
 - pointers **must always** point to variables/objects of the same type

A pointer **p** that stores the memory address of another variable **v** is said to **point** to **v**

Declaration of pointer variables

type *ptr_name;

Declaration of pointer variables

```
// can declare a single
// pointer (preferred)
int *p;

// can declare multiple
// pointers of the same type
int *p1, *p2;

// can declare pointers
// and other variables too
double *p3, var, *p4;
```

Pointer Operators

- Address-of operator
 - used to get the memory address of another variable/object

- Dereference Operator
 - used to get (or modify) the actual value of a given memory address (dereferencing a pointer)

Pointers and references

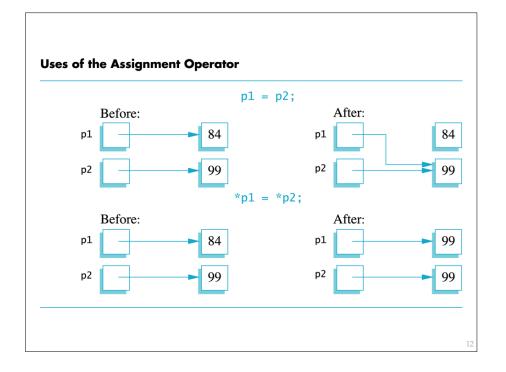

```
// Because the & symbol is included in the
  // declaration of a variable ~ we know that
  // myRef is a reference variable (& on left of = sign)
   int &myRef = a;
  // Because the & symbol is not included in the
    declaration of a variable ~ we know this is
  // the "get address" operator operating on myVar
  // (& NOT on left of = sign)
   std::cout << &myVar;</pre>
  // Because the * symbol is included in the
  // declaration of a variable ~ we know myPtr
  // is a pointer variable (* on left of = sign)
   int *myPtr = &a:
  // declaration of a variable ~ we know this is
  // the "dereference" operator operating on myPtr
→ std::cout << *mvPtr:</pre>
```

Pointers and references

- Not the same!
 - √ pointers are actual **variables**
 - ✓ references are *aliases* for existing variables
- Careful ... both use the ampersand operator (&)
 - ✓ references are **declared** using the ampersand (&)
 - √ **address-of** operator (&) is used with pointers

```
#include <iostream>
                             Assuming 32-bit words
int main() {
                                     Variable
                            Address
                                               Value
    int var = 10;
     int *ptr;
                           0x91340A08
     ptr = &var;
    *ptr = 20;
                           0x91340A0C
     // print both
                           0x91340A10
     // using cout
                           0x91340A14
     cout << var;
    cout << ptr;
                           0x91340A18
                           0x91340A1C
    cout << *ptr;</pre>
     return 0;
```

```
int main() {
                             Address
                                       Variable
                                                 Value
    int temp = 10;
    int value = 100;
    int *p1, *p2;
                            0x91340A08
                            0x91340A0C
    p1 = \&temp;
    *p1 += 10;
                            0x91340A10
                            0x91340A14
    p2 = &value;
                            0x91340A18
    *p2 += 5;
                            0x91340A1C
    p2 = p1;
                            0x91340A20
    *p2 += 5;
                               What is the status of
    return 0;
                             the stack at checkpoint a?
```

Null pointers and functions

- Pointers can be initialized to an "empty" address (points to nothing) using the nullptr keyword
 - ✓ **nullptr** is just a pointer literal
- Pointers can be passed as parameters to functions
 - ✓ pointers are treated as any other variable
 - √ just remember they are holding memory addresses

```
Address
                                             Variable
                                                        Value
#include <iostream>
                                  0x91340A08
void increment(int *ptr) {
                                  0x91340A0C
     (*ptr) ++;
                                  0x91340A10
                                  0x91340A14
int main() {
                                  0x91340A18
     int var = 10;
                                  0x91340A1C
                                  0x91340A20
     increment(&var);
                                  0x91340A24
     increment(&var);
                                  0x91340A28
                                  0x91340A2C
    // print using cout
                                  0x91340A30
                                  0x91340A34
     return 0;
```

Pointers and arrays

When declaring an array, the array name is treated as a **constant pointer** (pointing to the **base address**)

```
void zeros(int a[], int n){
    for (int i = 0; i < n; i ++){
        a[i] = 0;
    }
}
int main() {
    int array[5];
    zeros(array, 5);
    // do stuff
}</pre>
void zeros(int *a, int n) {
    for (int i = 0; i < n; i ++){
        a[i] = 0;
    }
}
int main() {
    int main() {
        int array[5];
        zeros(array, 5);
        // do stuff
}
</pre>
```

16

Pointer arithmetic

- As pointers hold **memory addresses** (basically integers), we can add integers to it
- · Must be careful!
 - ' p+1 does not add 1 byte to the memory address, it adds the size of the variable/literal type pointed by p

```
int *myPtr = &a;
myPtr is holding 0x7ffee7e44bcc
myPtr + 1 == 0x7ffee7e44bcc + 1 =
0x7ffee7e44bd0 (4 bytes were added)
```

· Can use pointer arithmetic to work with arrays

Example

- Print out a character array in reverse using pointer arithmetic
 - ✓ You can assume you have the length of the character array
